EPMAN

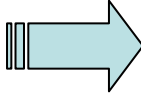

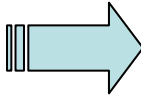

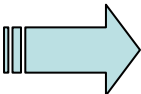

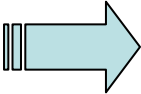

Expert Panel on Mitigation of Agriculture Nitrogen

Laura Valli

Building air wash methods

Emerging technologies

Bounds for abatement plants in livestock houses

- Natural ventilation 
- High variability in air flow rate during the year (more than 10 times) 
- Particulate matter in the air flow 
- Fairly complex plants, not familiar for farmers 
- High costs for channelling and fans
- Overdimensioning, energy consumption for ventilation
- PM abatement before treatment plant (increase costs and energy request)
- Risk that they are switched-off

When and where are they easier applicable?

- In very critical situation as a further reduction measure
- In country with strict air quality regulations (Germany, NL, ...)
- In tunnel ventilation houses (poultry farms)
- In treatment plants (composting, drying, NH_3 stripping,)

What techniques are available?

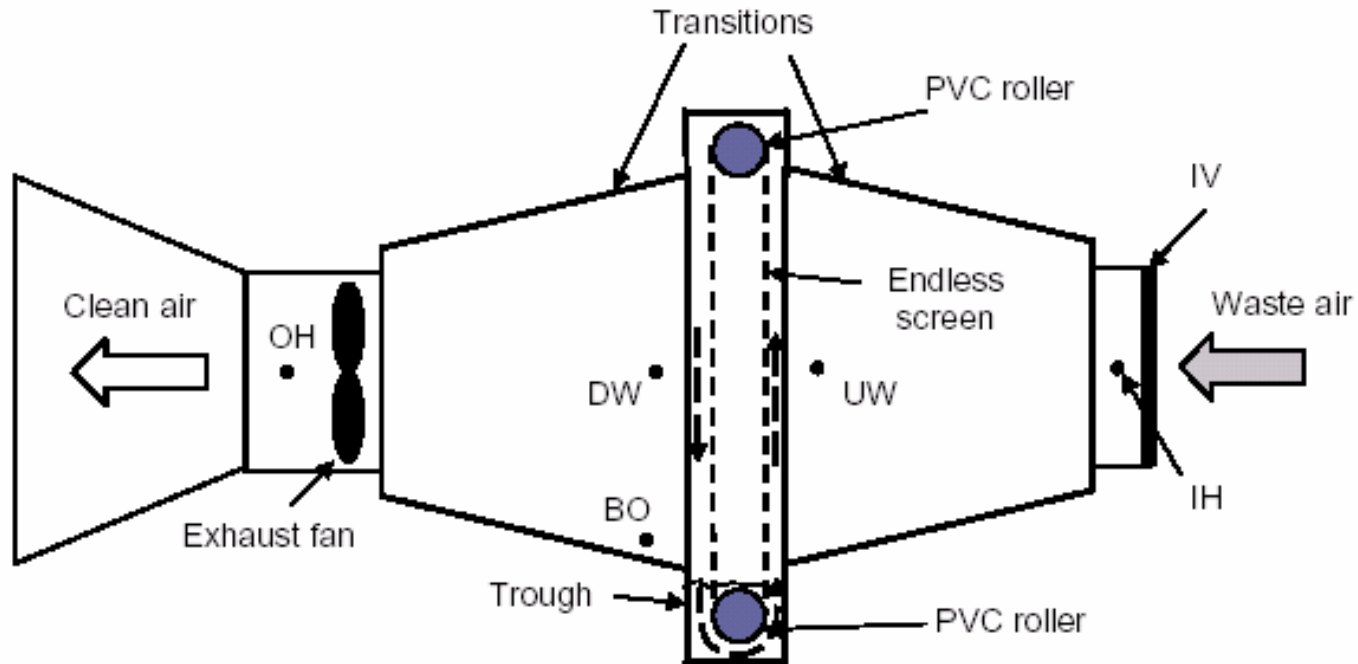

- Biofilters
- Trickle bed reactors (bioscrubbers)
- Chemical scrubber
- Multi-stage plants

The requirements in animal houses are:

- Simple and modular
- Low pressure drop

Modular chemical scrubber

Regenerative scrubber

NH₃ abatement efficiency = 58%

Low pressure drop < 100 Pa

Modular water air scrubber

Air flow rate reduction < 10%

PM abatement 40-60%

NH₃ removal = unsatisfactory

Costs = 0.5 € per pig produced

Single-stage techniques

Figure 1. Schematic of the exhaust air cleaning system for a broiler house.

Nozzle groups spray water on the front of the filter bank

Backview of the filter.
The exhaust air chimney
suck the air through the filter

PM abatement 45%

NH₃ removal = 78%

Multiple-stage techniques

source: KTBL publication 464

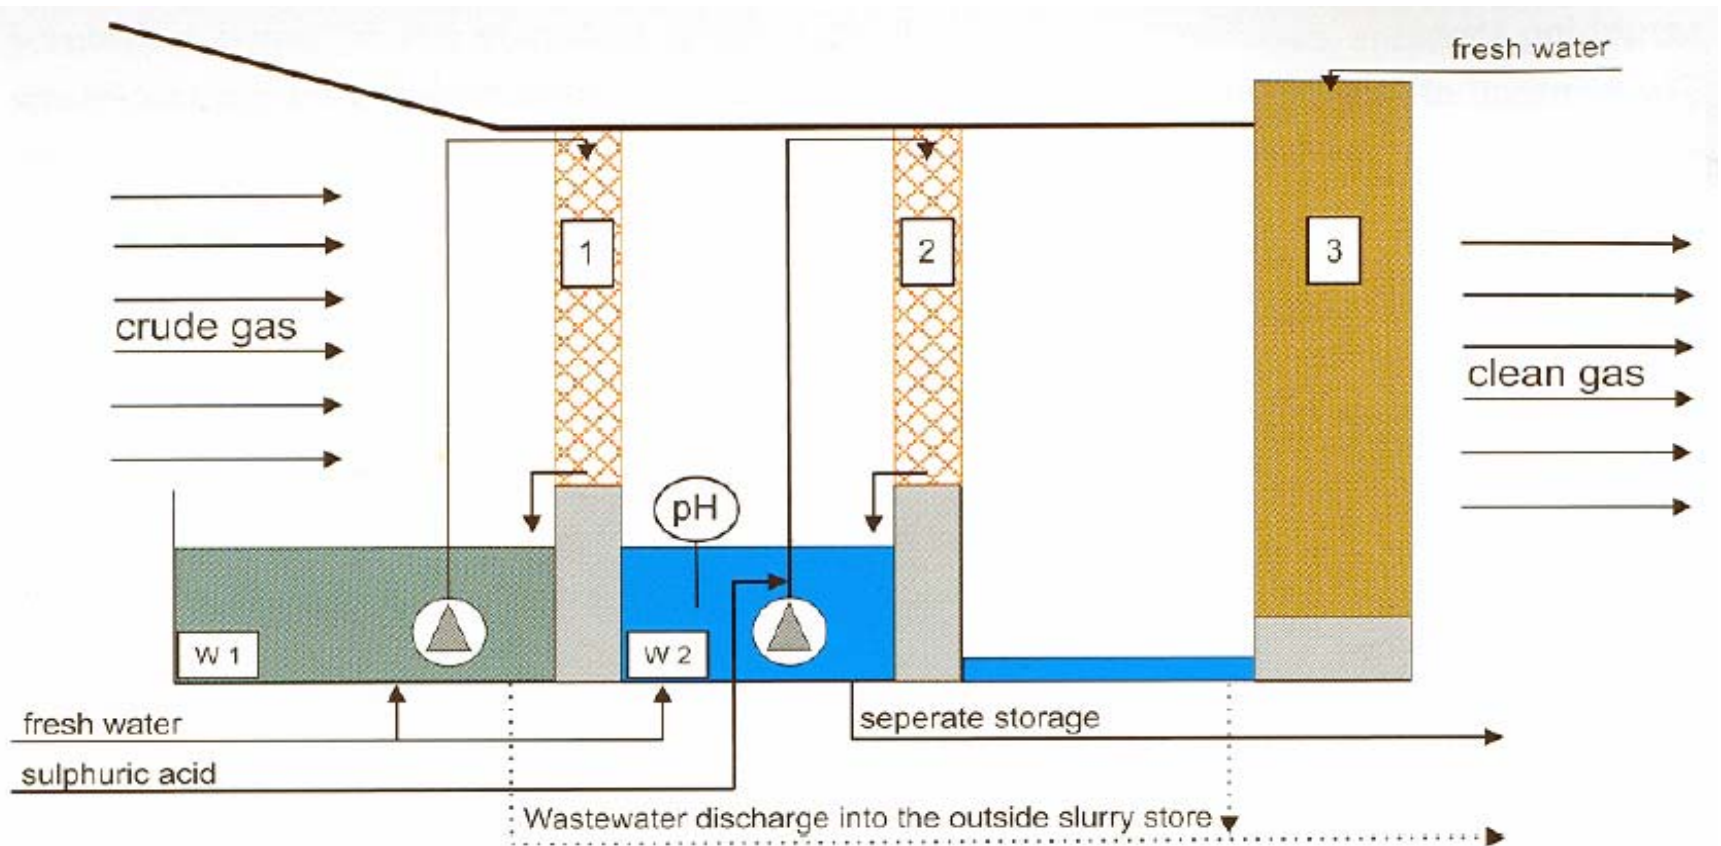

Figure 2.9: Design of a three-stage installation and its main functional elements

Multiple-stage techniques

Nozzle groups spray water on the front of the filter bank so that the dust cannot cling to the filter bank

A filter inspection isle lies between filter bank 1 and 2

The third element is a root timber and is used for the microbial transformation of odour-carrying agents

Removal efficiency

(from KTBL)

Technique	NH₃	Odour	PM
Biofilter	Not suitable	80-95%	> 70%
Bioscrubber	> 70%	> 70%	> 70%
Chemical scrubber	70-95%	30-50%	> 70%
Multi-stage	70-95%	70-90%	> 70%

Costs (KTBL analysis)

- Operational costs = 60% of total costs
- Of which:
 - Electricity = 45-50% (of which 50-70% for ventilation),
 - Acid, water and wastewater = 28-34%,
 - Labour (70-80 h/y) and repairs = 21-22%

Costs (Ogink & Bosma, NL)

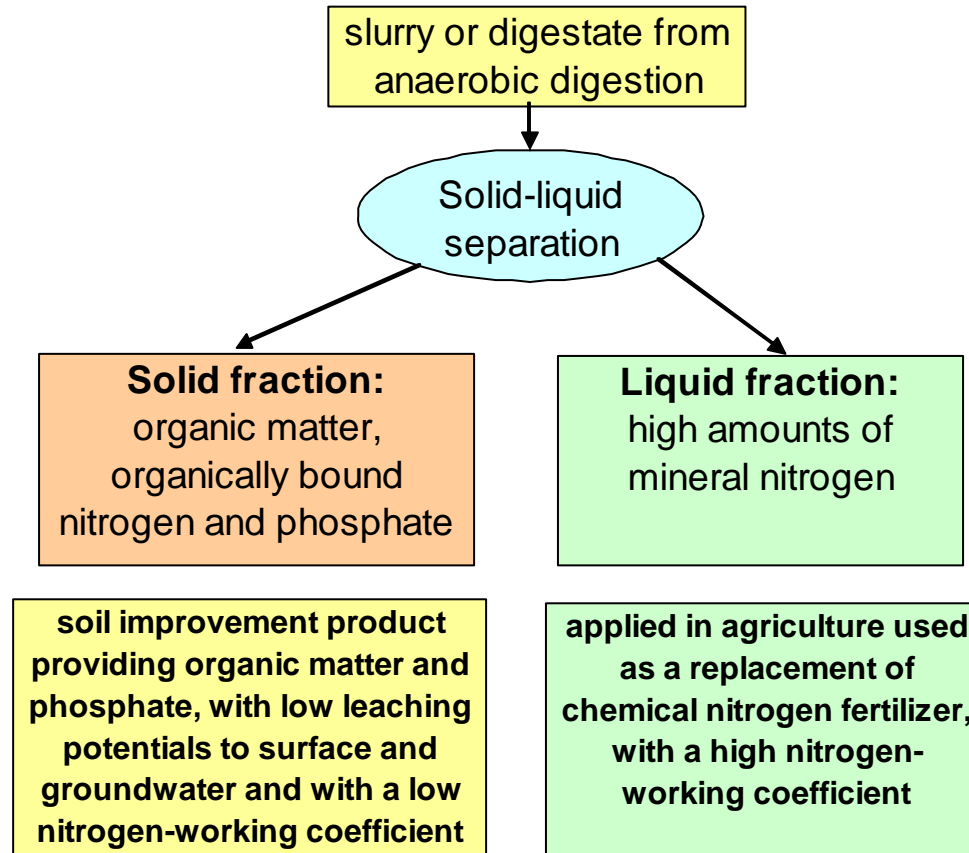

Fattening pigs [€/pig]	Construction	Low NH ₃ pen	Chem. scrubber	Multi-phase scrubber
Investment	New	38	35	47
	Modification	30	47	59
Operational	New	4.0	11.0	12.7
	Modification	6.3	15.0	16.2

Aspects to be considered

- Disposal of discharge solutions
- Pollution swapping (NH_3 converted in N_2O in biofilter,...)
- Increase in energy consumption
- Seasonal changes in ventilation rate (bypass, cooling)
- End-of-pipe techniques don't improve climate conditions of the housing (differently from BATs) and don't contribute to animal performance
- Risk that the farmer minimize ventilation rate
- Monitoring and recording by Local Authorities

Emerging techniques

Solid-liquid separation

Distribution by irrigators of clarified slurry mixed to irrigation water

- Digestate from anaerobic digestion mixed with irrigation water applied on maize with drip pipelines

Filtering group

Pipelines setting

Distribution by drip pipelines of digested slurry mixed to irrigation water

- High N uptake (20% higher than in the case of raw slurry applied at one time)

N input-output	Drip pipelines with slurry	Drip pipelines with water
Chemical fertilizer	78	78
Slurry	194	245
Total N input	272	323
N uptake	290	247

Distribution of digested slurry mixed to irrigation water

Very low NH_3 emissions (< 5% N_{tot})

Ammonia emissions are strongly reduced (up to 80%) with reference to an application of raw slurry by the same system

Emerging techniques: PM abatement

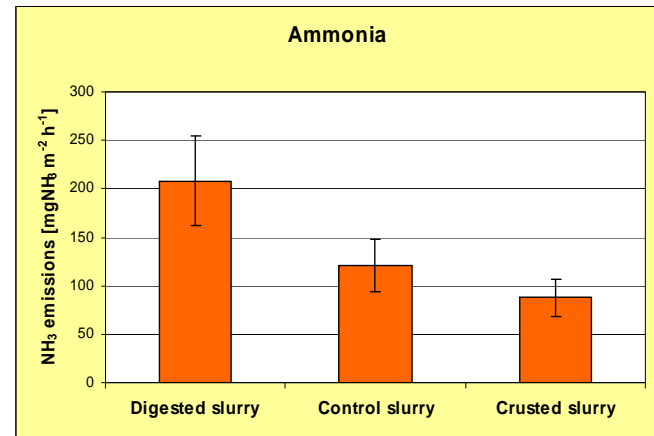

Big Dutchman system

Emerging techniques: anaerobic digestion

Emissions from anaerobic digested cattle slurry

Poultry manure drying tunnel

	NH ₃ [kg head ⁻¹ y ⁻¹]	N ₂ O [kg head ⁻¹ y ⁻¹]	CH ₄ [kg head ⁻¹ y ⁻¹]	CO ₂ [kg head ⁻¹ y ⁻¹]

Low protein diet in fattening pigs

Finishing pigs from 100 to 160 kg (6 pen with 12 pig per pen, 2 fattening cycles)

Parameter	Unit	Standard diet	Low protein diet	Standard diet	Low protein diet
Protein in diet	[% wb]	14	12	13	9
ICA	[kg _{feed} /kg _{meat}]	3.9	4.0	3.9	4.0
N excreted	[kg/pig place/y]	17.8	14.1	17.1	10.8
N emitted from pig house	[kg/pig place/y]	3.2	2.3	3.1	1.4

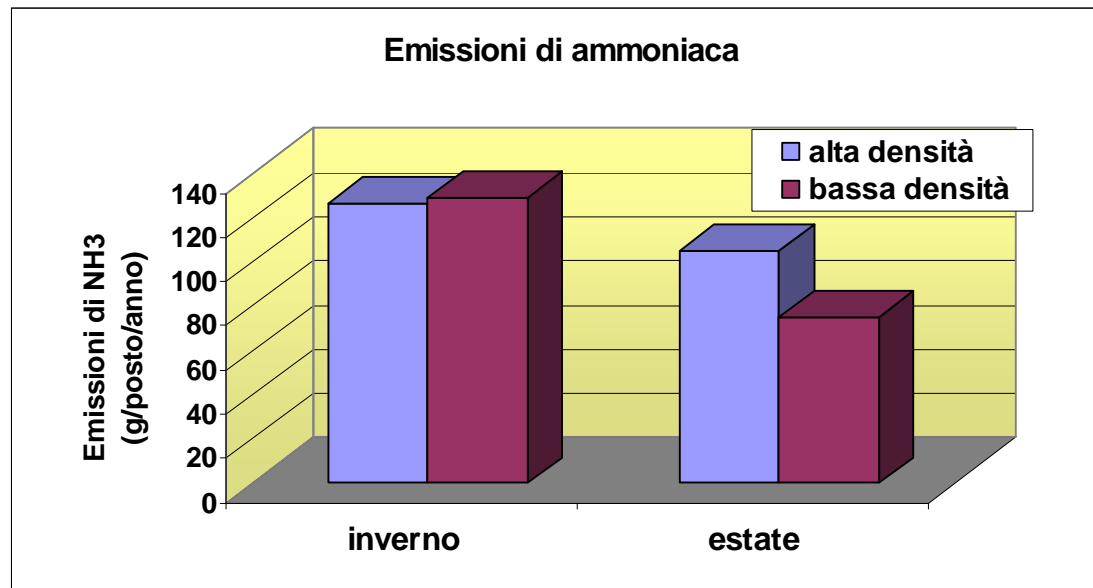

Animal welfare (broiler and turkey)

- Higher bird density cause wetter litter and crust formation, worsening animal health (foot dermatitis) and welfare, but lower density..

Animal welfare (broiler and turkey)

- may have negative effects on NH₃ emissions, especially in winter, when the air flow rate is reduced and the litter crust make a cap for the emissions

Animal welfare (pigs)

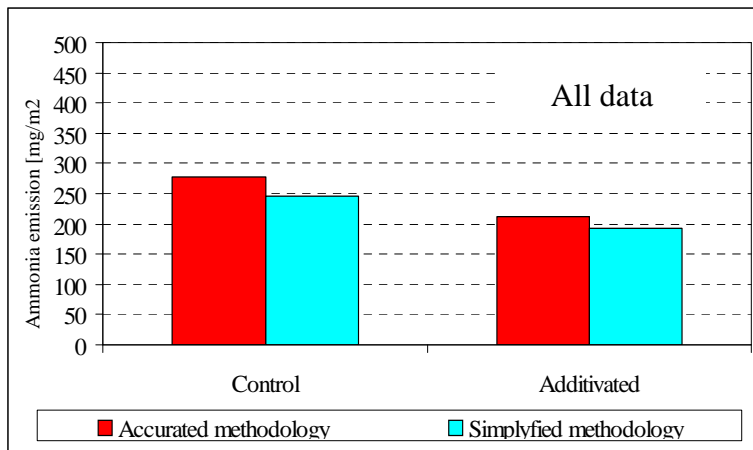

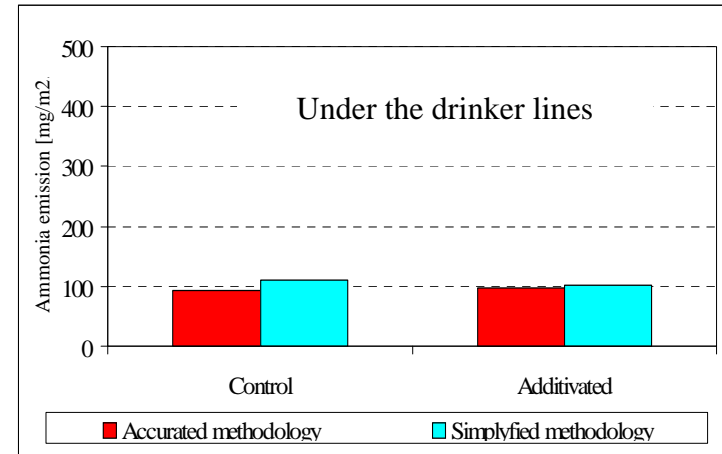

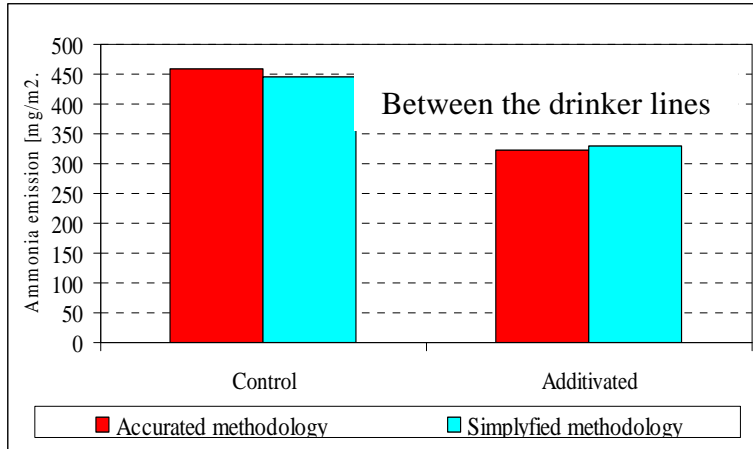

Directive 2001/88/EC on pig welfare establishes a maximum width of 18 mm for openings in slatted flooring used for groups of rearing pigs.

In the case of finishing pigs over 110 kg, a maximum opening width of 20-22 mm is usually adopted to speed up manure discharge and reduce fouling of both the floor and the animal skin

Additives (poultry litter)

Ammonia emissions [mg/m².h]

Results:

in the BDL portions the emissions from the treated litter were 27-30% lower than the control, while in the UDL portions the additive efficiency is not evident.

With a weighted average the additive efficiency was circa 25%

Materials and methods

two strips of litter were identified in a house for broilers close to the end of their fattening cycle

★ Under the Drinkers Lines (UDL)

★ Intra the Drinkers Lines (IDL)

Device used for ammonia emission measurements

The measurement technique is based on the “static air chamber method” for flux measurements
